AMENDMENTS TO THE CLAIMS

Please amend the claims as follows.

1. (Currently Amended) A testing device for testing an electronic device, comprising:

a deterministic jitter application unit operable to apply deterministic jitter to a given input

signal without causing an amplitude modulation component and supply said input signal to said

electronic device;

a jitter amount controller operable to control magnitude of said deterministic jitter

generated by said deterministic jitter application unit; and

a determination unit operable to determine whether or not said electronic device is

defective based on an output signal output from said electronic device in accordance with said

input signal.

wherein said jitter amount controller determines said magnitude of said deterministic

jitter based on a threshold value of a peak-to-peak value of alignment jitter between said input

signal and a recovered clock signal recovered by said electronic device from said input signal.

2. (Original) A testing device as claimed in claim 1, wherein said deterministic jitter application

unit includes a primary filter operable to transmit said input signal and generate said

deterministic jitter.

3. (Original) A testing device as claimed in claim 1, wherein said deterministic jitter application

unit includes a cable operable to transmit said input signal and generate said deterministic jitter.

4. (Canceled)

317716-1

3

(Original) A testing device as claimed in claim 1, further comprising a sinusoidal jitter application unit operable to apply sinusoidal jitter to said input signal, wherein

said jitter amount controller further controls magnitude of said sinusoidal jitter generated by said sinusoidal jitter application unit.

6. (Original) A testing device as claimed in claim 5, wherein said jitter amount controller determines said magnitude of said sinusoidal jitter based on a threshold value of a peak-to-peak value of alignment jitter between said input signal and a recovered clock signal recovered by said electronic device from said input signal, and a jitter transfer function in a nondefective electronic device.

7. (Original) A testing device as claimed in claim 6, wherein said jitter amount controller determines said magnitude of said sinusoidal jitter based on a sinusoidal jitter threshold value obtained by multiplying said threshold value of said peak-to-peak value of said alignment jitter by a sinusoidal jitter ratio that is predetermined, and said jitter transfer function, and

determines said magnitude of said deterministic jitter based on a deterministic jitter threshold value obtained by subtracting said sinusoidal jitter threshold value from said threshold value of said peak-to-peak value of said alignment jitter, and said jitter transfer function.

8. (Original) A testing device as claimed in claim 6, wherein said jitter amount controller includes a jitter transfer function estimation unit operable to obtain said jitter transfer function based on a timing jitter series of said input signal and a timing jitter series of said recovered clock signal recovered by said electronic device from said input signal.

317716-1

9. (Original) A testing device as claimed in claim 6, wherein said sinusoidal jitter application

unit applies said sinusoidal jitter having a plurality of frequency components to said input signal,

and

said jitter amount controller determines magnitude of each of said frequency components

of said sinusoidal jitter based on said threshold value of said peak-to-peak value of said

alignment jitter and said jitter transfer function.

10. (Original) A testing device as claimed in claim 9, wherein said jitter amount controller

determines said magnitude of each of said plurality of frequency components of said sinusoidal

jitter based on a frequency-component threshold value obtained by multiplying said threshold

value of said peak-to-peak value of said alignment jitter by a frequency-component ratio that is

predetermined for that frequency component, and said jitter transfer function, and

determines said magnitude of said deterministic jitter based on a deterministic jitter

threshold value obtained by subtracting a sum of said frequency-components threshold values

corresponding to said plurality of frequency components, from said threshold value of said peak-

to-peak value of said alignment jitter.

11. (Original) A testing device as claimed in claim 1, wherein said electronic device receives

said input signal and a reference clock signal as its input and samples said input signal based on

said reference clock signal, wherein said testing device further comprises a phase shifter

operable to shift a phase of said reference clock signal.

12. (Original) A testing device for testing an electronic device, comprising:

317716-1

a sinusoidal jitter application unit operable to apply sinusoidal jitter to a given input signal and supply said input signal with said sinusoidal jitter to said electronic device;

a jitter amount controller operable to control magnitude of said sinusoidal jitter applied by said sinusoidal jitter application unit; and

a determination unit operable to determine whether or not said electronic device is defective based on an output signal output from said electronic device in accordance with said input signal, wherein

said jitter amount controller determines said magnitude of said sinusoidal jitter based on a threshold value of a peak-to-peak value of alignment jitter between said input signal and a recovered clock signal recovered by said electronic device from said input signal, and a jitter transfer junction in said electronic device that is nondefective.

13. (Currently Amended) A testing method for testing an electronic device, comprising:

applying deterministic jitter to a given input signal without causing an amplitude modulation component and supplying said input signal with said deterministic jitter to said electronic device;

controlling magnitude of said deterministic jitter applied in the application of said deterministic jitter; and

determining whether or not said electronic device is defective based on an output signal output from said electronic device in accordance with said input signal,

wherein the magnitude of the deterministic jitter is determined based on a threshold value of a peak-to-peak value of alignment jitter between said input signal and a recovered clock signal recovered by said electronic device from said input signal.

317716-1 6

14. (Original) A testing method as claimed in claim 13, wherein said deterministic jitter is

generated by using a primary filter that transmit said input signal in said application of said

deterministic jitter.

15. (Original) A testing method as claimed in claim 13, wherein said deterministic jitter is

generated by using a cable that transmits said input signal in said application of said

deterministic jitter.

16. (Original) A testing method as claimed in claim 13, further comprising applying sinusoidal

jitter to said input signal.

17. (Original) A testing method as claimed in claim 16, wherein said sinusoidal jitter having a

plurality of frequency components is applied to said input signal in said application of said

sinusoidal jitter.

18. (Original) A testing method for testing an electronic device, comprising:

applying sinusoidal jitter to a given input signal and supplying said input signal with said

sinusoidal jitter to said electronic device;

controlling magnitude of said sinusoidal jitter applied in said application of said

sinusoidal jitter; and

determining whether or not said electronic device is defective based on an output signal

output from said electronic device in accordance with said input signal, wherein

said controlling of said magnitude of said sinusoidal jitter determines said magnitude of

said sinusoidal jitter based on a threshold value of a peak-to-peak value of alignment jitter

317716-1

7

between said input signal and a recovered clock signal recovered by said electronic device from said input signal, and a jitter transfer function of said electronic device that is nondefective.
